Top Tips and Recommendations for use of Sodium Glucose

NHS Kent and Medway

Co-transporter 2 inhibitors (SGLT2i) in Adults with Type 2 Diabetes (T2DM) for Glycaemic Control

# **INTRODUCTION & SCOPE**

- Updated NICE T2DM guidelines [NG28, June 2022] highlight increased recommendations for SGLT2 inhibitor use for adults with T2DM
- The SGLT2i class have a growing evidence base for cardio +/- renal protective effects independent of glycaemic effectiveness. Further data is emerging rapidly, and this may be reflected in ongoing licensing changes for individual members of this class. Please see section on "SGLT2i Use in HF and CKD" on page 3 for more information

### Aims of this document:

- To guide prescribing of SGLT2 inhibitors within each individual drug's current license for glycaemic control in T2DM alongside appropriate clinical guidelines, such as NG28
- To ensure safe prescribing of SGLT2 inhibitors for patients with type 2 diabetes for the management of glycaemic control
- To ensure these agents are prescribed appropriately and that the necessary safety information is given to all patients

\*It is important to note this is only a guide and not exhaustive, appropriate clinical judgement and referral to other reference sources may be appropriate in individual patient cases

## What are SGLT2 Inhibitors?

- · An established class of medications for the treatment of diabetes which act by preventing the absorption of glucose and
- sodium, mainly from the proximal renal tubule in the kidney
- Glucose and sodium are, therefore, lost in urine
- People do not become hyponatraemic (unless also on diuretics) as most of the sodium is reabsorbed in the distal tubule
- This effect results in decreasing the blood glucose level, weight loss, an osmotic diuresis and a drop in blood pressure. These drugs have been licensed and used widely in people with T2DM and have shown significant cardiovascular and renal benefits in different subsets of this group of patients

# When Initiating SGLT2 Inhibitors: Prescribing Considerations also see here

- Minimise risk of hypoglycaemia:
  - Review glucose lowering medications that may cause hypoglycaemia (e.g., insulin and sulphonylureas)
  - Consider dose reductions of above when SGLT2i initiated, particularly if HbA1c is already at target
- Minimise risk of Diabetic Ketoacidosis (DKA), check if the person may be at increased risk, for example if:
  - They have had a previous episode of DKA
  - They are unwell with intercurrent illness
- They are following a very low carbohydrate or ketogenic diet (20-50g/day of carbohydrate or <10% of a 2000 kcal/day diet) • Minimise risk of hypotension:
  - Review diuretic and anti-hypertensives if hypertension improves or if there is postural hypotension

Monitoring Requirements	Pregnancy and Breast- feeding					
<ul> <li>Additional monitoring after starting SGLT2 inhibitors is NOT required</li> <li>Routine monitoring of kidney function should continue as part of routine care, frequency guided by national and local guidance for T2DM, and in line with person's other co-morbidities as appropriate. Additional routine tests are not required after starting SGLT2i</li> <li>Note glycaemic benefit will be limited for all SGLT2i below eGFR of 45ml/min as the glucose lowering efficacy of SGLT2i therapy is dependent on renal function. Further glycaemic control may be required.</li> </ul>						
When Initiating SGLT2 Inhibitors:	Reducing Risk: Patient Education, Sick Day Rules	<b>*</b> *				
<ul> <li>Before initiating SGLT2 inhibitors the patient should be advised:</li> <li>What the benefits of taking SGLT2 inhibitors are to the as an individual</li> <li>What side effects may occur (see "Class Side Effects" on page 3) and sick day rules (see box to right) and when to</li> <li>What side effects may occur (see "class Side Effects" on page 3) and sick day rules (see box to right) and when to</li> <li>What side effects may occur (see "class Side Effects" on page 3) and sick day rules (see box to right) and when to</li> <li>What side effects may occur (see "class Side Effects" on page 3) and sick day rules (see box to right) and when to</li> </ul>						

- Restart only AFTER eating normally for AT LEAST 24 HOURS <u>AND</u> no longer acutely unwell
- Encourage patient to avoid dehydration with appropriate fluid intake
- ALL patients must be counselled on the risk of ketoacidosis and signs and symptoms of this (nausea, vomiting, abdominal pain, stupor, fatigue, difficulty breathing) and to STOP SGLT2 inhibitor if any symptoms develop
- Seek medical advice if particularly unwell with infection or illness
- To seek urgent medical attention if symptoms of Fournier's gangrene (e.g., severe pain, tenderness, erythema, swelling in genital or perineal area)
  - Stop SGLT2 inhibitors prior to surgery as advised by pre-op team

- stop taking their SGLT2 inhibitor due to associated risks with dehydration and development of DKA
  - To seek urgent medical attention if symptoms of DKA
  - To seek urgent medical attention if symptoms of Fournier's gangrene (e.g., severe pain, tenderness, erythema, swelling in genital or perineal area)
- About the importance of **routine preventative foot care**
- To drink plenty of fluids to avoid dehydration unless they have been told to restrict fluids by a healthcare professional, for example due to heart or kidney problems

## Top Tips and Recommendations for use of Sodium Glucose Co-transporter 2 inhibitors (SGLT2i) in people with Type 2 Diabetes (T2DM) For Glycaemic Control

## Who is most likely to benefit most from SGLT2 inhibitor treatment?

It is important to select the right patient for SGLT2 inhibitor therapy and avoid in others who may be at high risk of DKA The following patients are likely to benefit most:

- Adults above 18 years with T2DM and one or more of the following:
  - established/high risk of atherosclerotic cardiovascular disease (NICE guidance NG28 advises SGLT2i use with proven cardiovascular benefit in people with QRISK2 of 10% or higher)
    - People who qualify for a statin due to diabetes will qualify for SGLT2i therapy
    - NICE define established atherosclerotic CVD as: coronary heart disease, acute coronary syndrome, previous myocardial infarction, stable angina, prior coronary or other revascularisation, cerebrovascular disease (ischaemic stroke and transient ischaemic attack) and peripheral arterial disease.
    - chronic kidney disease (CKD)
  - heart failure (HF)
  - inadequate glycaemic control with need to minimise hypoglycaemia
  - inadequate glycaemic control with need to minimise weight gain / encourage weight loss
- Patients with a clear understanding of the risks associated with SGLT2 inhibitors, how to reduce those risks and ability to follow sick day rules

### Who is likely to be at risk with SGLT2 inhibitors?

### Use with CAUTION in the following situations:

### Patient Characteristics:

- Body mass index <27 kg/m<sup>2</sup> although diabetes and other specialists may use them in people with lower BMI for potential cardiac or renal benefits
- Recent weight loss
- Potential for pregnancy
- People at risk of hypotension/hypovolaemia (e.g., on diuretic and/or multiple antihypertensive therapies, elderly)
- People diagnosed with or at risk of frailty
- Cognitive impairment or use of medication compliance aid (as this may imply inadequate understanding required to follow sick day rules and take action to prevent and identify DKA)

#### **Other Past Medical History:**

- On long term or recurrent courses of steroids
- Raised haematocrit
- Severe hepatic impairment
- Recurrent urinary or genital tract infections

### Diabetes History:

- Long duration of diabetes (generally over 10 years from diagnosis)
- Person with very high level of HbA1c >86 mmol/mol
- Person considered at high risk of acute effects of hyperglycaemia (e.g., dehydration due to nonadherence to medication)
- Past history of active foot disease/foot ulceration – consider discussion with specialist, ensure regular preventative footcare\*
- Existing diabetic foot ulcers\*
- Previous lower limb amputation\*
- History of peripheral arterial disease (PAD)\*
- Taking sulphonylureas and/or insulin increased risk of hypoglycaemia if commenced on SGLT2i

\*Caution is in line with MHRA alert (see link below) based on CANVAS study on canagliflozin. Later studies and real world metanalysis for canagliflozin reported no increased risk of lower limb amputations. Not seen in other SGLT2i.

https://www.gov.uk/drug-safety-update/sglt2-inhibitors-updatedadvice-on-increased-risk-of-lower-limb-amputation-mainly-toes

## AVOID in the following situations:

- Patient Characteristics:
   Age <18 years</li>
  - Pregnant, breastfeeding, female in their child-bearing years and sexually active without contraception
  - Person with excess alcohol consumption or IVDU
  - History of allergic reaction to SGLT2i or any of their excipients
  - Person adhering to a fasting diet or ketogenic, low calorie, or low carbohydrate diet (including in context of strenuous exercise)
- (20-50g/day of carbohydrate or <10% of 2000 kcal/day diet)
  Diabetes History:
  - Suspected or possible T1DM unless under specialist advice, noting this is 'off-label' use
  - Past history of diabetic ketoacidosis unless under specialist advice, noting this is 'off-label' use
  - Any diagnosis or suspicion of latent autoimmune diabetes (LADA), other genetic causes of diabetes, known pancreatic disease or injury, or people who rapidly progressed to needing insulin within 1 year of diagnosis

#### **Current Medical History:**

- Acutely unwell person (acute medical illness including COVID-19, surgery or planned medical procedure)
- Active foot disease
- Inpatient with acute vascular event who is not stable
- Eating disorder
- eGFR outside than allowed in the up-todate licensing of the medication being considered
- Already on SGLT2 inhibitor for other comorbidity
- Organ transplant
- Patients receiving dialysis

Output         Output         And the set of th			Dose Adjustments (When using in T2DM for allocaemic control. Please note licenses you, for other indications please check individual drug SPC)
